Math 675 Spring 2026:
Homework 3 (LATE)
Due Tuesday, February 10th, 2026

Question 1:

a) $\mathbf{x}' = \begin{pmatrix} \frac{5}{4} & \frac{3}{4} \\ \frac{3}{4} & \frac{5}{4} \end{pmatrix} \mathbf{x}$

$$\begin{vmatrix} \frac{5}{4} - \lambda & \frac{3}{4} \\ \frac{3}{4} & \frac{5}{4} - \lambda \end{vmatrix} = \left(\tfrac{5}{4} - \lambda\right)^2 - \left(\tfrac{3}{4}\right)^2 = 0$$

$$= \left(\tfrac{5}{4} - \lambda + \tfrac{3}{4}\right)\left(\tfrac{5}{4} - \lambda - \tfrac{3}{4}\right) = 0$$

$$= (2 - \lambda)\left(\tfrac{1}{2} - \lambda\right) = 0$$

$$\Rightarrow \lambda_1 = 2, \lambda_2 = \tfrac{1}{2}$$

Eigenvalue #1

$$\lambda_{\mathbf{1}} = \quad \mathbf{2} : \begin{bmatrix} \frac{5}{4} - \lambda_1 & \frac{3}{4} \\ \frac{3}{4} & \frac{5}{4} - \lambda_1 \end{bmatrix} \to \begin{bmatrix} -\frac{3}{4} & \frac{3}{4} \\ \frac{3}{4} & -\frac{3}{4} \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{aligned} -1v_1 + 1v_2 &= 0 \\ 1v_1 - 1v_2 &= 0 \end{aligned} \longrightarrow \quad v_1 = v_2 \quad \longrightarrow \mathbf{v}_1 = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

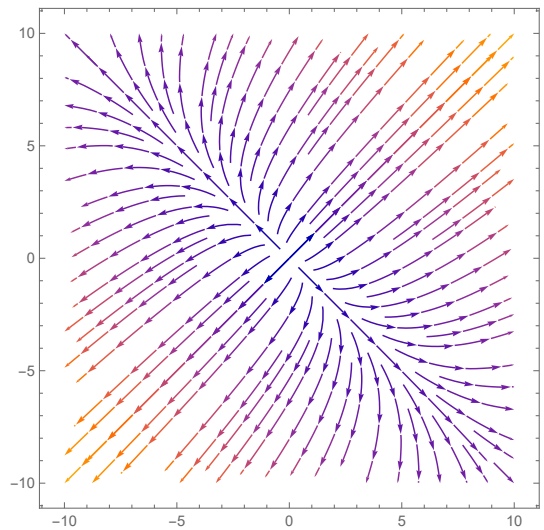
Eigenvalue #2

$$\lambda_{\mathbf{2}} = \quad \frac{\mathbf{1}}{\mathbf{2}} : \begin{bmatrix} \frac{5}{4} - \lambda_2 & \frac{3}{4} \\ \frac{3}{4} & \frac{5}{4} - \lambda_2 \end{bmatrix} \to \begin{bmatrix} \frac{3}{4} & \frac{3}{4} \\ \frac{3}{4} & \frac{3}{4} \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{aligned} 1v_1 + 1v_2 &= 0 \\ 1v_1 + 1v_2 &= 0 \end{aligned} \longrightarrow \quad v_1 = -v_2 \quad \longrightarrow \mathbf{v}_2 = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

So our general solution is $\mathbf{x} = c_1 \begin{pmatrix} 1 \\ 1 \end{pmatrix} e^{2t} + c_2 \begin{pmatrix} -1 \\ 1 \end{pmatrix} e^{\frac{1}{2}t}$

If we take the limit as t approaches infinity, we can notice both terms head to infinity, but notice that the dominant term is the one with $\lambda_1 = 2$, so all trajectories will be parellel to the line $y = x$



b) $\mathbf{x}' = \begin{pmatrix} 4 & -3 \\ 8 & -6 \end{pmatrix} \mathbf{x}$

$$\begin{vmatrix} 4-\lambda & -3 \\ 8 & -6-\lambda \end{vmatrix} = (4-\lambda)(-6-\lambda) - (-3)(8) = 0$$

$$= -24 - 4\lambda + 6\lambda + \lambda^2 + 24 = 0$$

$$= \lambda^2 + 2\lambda = 0$$

$$\Rightarrow \lambda_1 = 0, \lambda_2 = -2$$

Eigenvalue #1

$$\lambda_{\mathbf{1}} = \quad \mathbf{0} : \begin{bmatrix} 4-\lambda_1 & -3 \\ 8 & -6-\lambda_1 \end{bmatrix} \rightarrow \begin{bmatrix} 4 & -3 \\ 8 & -6 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{aligned} 4v_1 - 3v_2 &= 0 \\ 8v_1 - 6v_2 &= 0 \end{aligned} \longrightarrow \quad 4v_1 = 3v_2 \quad \longrightarrow \mathbf{v}_1 = \begin{bmatrix} 3 \\ 4 \end{bmatrix}$$

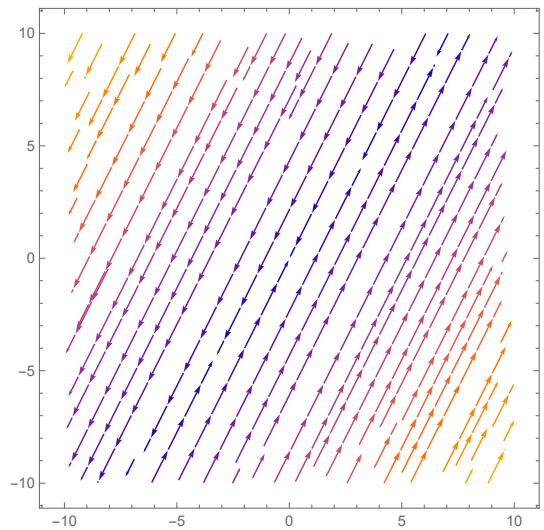
Eigenvalue #2

$$\lambda_{\mathbf{2}} = -\mathbf{2} : \begin{bmatrix} 4-\lambda_2 & -3 \\ 8 & -6-\lambda_2 \end{bmatrix} \rightarrow \begin{bmatrix} 6 & -3 \\ 8 & -4 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{aligned} 6v_1 - 3v_2 &= 0 \\ 8v_1 - 4v_2 &= 0 \end{aligned} \longrightarrow \quad 2v_1 = v_2 \quad \longrightarrow \mathbf{v}_2 = \begin{bmatrix} 1 \\ 2 \end{bmatrix}$$

So our general solution is $\mathbf{x} = c_1 \begin{pmatrix} 1 \\ 1 \end{pmatrix} e^{2t} + c_2 \begin{pmatrix} -1 \\ 1 \end{pmatrix} e^{\frac{1}{2}t}$

If we take the limit as t approaches infinity, we can notice both terms head to infinity, but notice that the dominant term is the one with $\lambda_1 = 2$, so all trajectories will be parellel to the line $y = x$



c) $\mathbf{x}' = \begin{pmatrix} 3 & -2 \\ 4 & -1 \end{pmatrix} \mathbf{x}$

$$\begin{vmatrix} 3-\lambda & -2 \\ 4 & -1-\lambda \end{vmatrix} = (3-\lambda)(-1-\lambda) - (-2)(4) = 0$$

$$= -3 - 3\lambda + \lambda + \lambda^2 + 8 = 0$$

$$= \lambda^2 - 2\lambda + 5 = 0$$

$$\Rightarrow \lambda_1 = 1 + 2i, \lambda_2 = 1 - 2i$$

Eigenvalue #1

$$\lambda_{\mathbf{1}} = \mathbf{1} + \mathbf{2i} : \begin{bmatrix} 3-\lambda_1 & -2 \\ 4 & -1-\lambda_1 \end{bmatrix} \to \begin{bmatrix} 2-2i & -2 \\ 4 & -2-2i \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{aligned} (2-2i)v_1 - 2v_2 &= 0 \\ 4v_1 - (2+2i)v_2 &= 0 \end{aligned} \longrightarrow \quad v_2 = (1-i)v_1 \quad \longrightarrow \mathbf{v}_1 = \begin{bmatrix} 1 \\ 1-i \end{bmatrix}$$

So our general solution is $\mathbf{x} = c_1 \begin{pmatrix} 1 \\ 1-i \end{pmatrix} e^{(1+2i)t}$

This just looks bad and its hard to interpret, so let's use Euler's formula to rewrite it in a better way:

$$\begin{pmatrix} 1 \\ 1-i \end{pmatrix} e^{(1+2i)t} = \begin{pmatrix} 1 \\ 1-i \end{pmatrix} e^t e^{2it} = \begin{pmatrix} 1 \\ 1-i \end{pmatrix} e^t(\cos(2t) + i\sin(2t))$$

$$= e^t \left[\begin{pmatrix} \cos(2t) + i\sin(2t) \\ (1-i)(\cos(2t) + i\sin(2t)) \end{pmatrix} \right]$$

$$= e^t \left[\begin{pmatrix} \cos(2t) \\ \cos(2t) + \sin(2t) \end{pmatrix} + i \begin{pmatrix} \sin(2t) \\ \sin(2t) - \cos(2t) \end{pmatrix} \right]$$

$$= c_1 e^t \left[\begin{pmatrix} \cos(2t) \\ \cos(2t) + \sin(2t) \end{pmatrix} \right] + c_2 e^t \left[\begin{pmatrix} \sin(2t) \\ \sin(2t) - \cos(2t) \end{pmatrix} \right]$$

$$= c_1 e^t \left[\begin{pmatrix} 1 \\ 1 \end{pmatrix} \cos 2t - \begin{pmatrix} 0 \\ -1 \end{pmatrix} \sin 2t \right] + c_2 e^t \left[\begin{pmatrix} 0 \\ -1 \end{pmatrix} \cos 2t + \begin{pmatrix} 1 \\ 1 \end{pmatrix} \sin 2t \right]$$

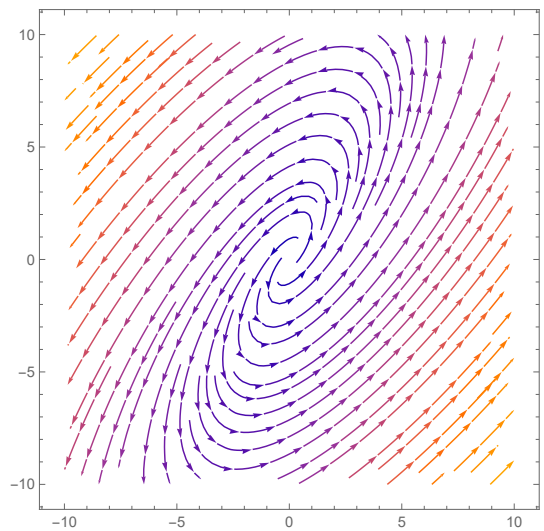
Notice that the vectors in front of the sins and cosines are components of the eigenvector that we started with:

$$\mathbf{v}_1 = \begin{bmatrix} 1 \\ 1-i \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix} + i \begin{bmatrix} 0 \\ -1 \end{bmatrix}$$

This is a spiral source, so all trajectories will spiral outwards from the origin.

Since going through all of that work with complex eigenvalues, I wonder if we could build a potential shortcut? If $\lambda = \mathbf{a} + \mathbf{b}i$ is an eigenvalue of A with eigenvector $\mathbf{v} = \mathbf{c} + i\mathbf{d}$, then we maybe can write the solution as

$$\mathbf{x}(t) = e^{\mathbf{a}t}(\mathbf{c}\cos(\mathbf{b}t) - \mathbf{d}\sin(\mathbf{b}t)) + e^{\mathbf{a}t}(\mathbf{d}\sin(\mathbf{b}t) + \mathbf{c}\cos(\mathbf{b}t))$$



d) $\mathbf{x}' = \begin{pmatrix} 2 & -\frac{5}{2} \\ \frac{9}{5} & -1 \end{pmatrix} \mathbf{x}$

$$\begin{vmatrix} 2-\lambda & -\frac{5}{2} \\ \frac{9}{5} & -1-\lambda \end{vmatrix} = (2-\lambda)(-1-\lambda) - (-\tfrac{5}{2})(\tfrac{9}{5}) = 0$$

$$= -2 - 2\lambda + \lambda + \lambda^2 + \tfrac{9}{2} = 0$$

$$= \lambda^2 - \lambda + \tfrac{5}{2} = 0$$

$$\Rightarrow \lambda_1 = \tfrac{1}{2} + \tfrac{3}{2}i, \lambda_2 = \tfrac{1}{2} - \tfrac{3}{2}i$$

Eigenvalue #1

$$\lambda_{\mathbf{1}} = \frac{\mathbf{1}}{\mathbf{2}} + \frac{\mathbf{3}}{\mathbf{2}}\mathbf{i} : \begin{bmatrix} 2-\lambda_1 & -\frac{5}{2} \\ \frac{9}{5} & -1-\lambda_1 \end{bmatrix} \to \begin{bmatrix} \frac{3}{2} - \frac{3}{2}i & -\frac{5}{2} \\ \frac{9}{5} & -\frac{3}{2} - \frac{3}{2}i \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{aligned} (\tfrac{3}{2} - \tfrac{3}{2}i)v_1 - \tfrac{5}{2}v_2 &= 0 \\ \tfrac{9}{5}v_1 - (-\tfrac{3}{2} + \tfrac{3}{2}i)v_2 &= 0 \end{aligned} \to \quad (3-3i)v_1 = 5v_2 \quad \to \mathbf{v}_1 = \begin{bmatrix} 5 \\ 3-3i \end{bmatrix}$$

So our general solution is $\mathbf{x} = c_1 \begin{pmatrix} 5 \\ 3-3i \end{pmatrix} e^{(\frac{1}{2}+\frac{3}{2}i)t}$

This just looks bad and its hard to interpret, so let's use Euler's formula to rewrite it in a better way:

$$\begin{pmatrix} 5 \\ 3-3i \end{pmatrix} e^{(\frac{1}{2}+\frac{3}{2}i)t} = \begin{pmatrix} 5 \\ 3-3i \end{pmatrix} e^{\frac{1}{2}t} e^{\frac{3}{2}it} = \begin{pmatrix} 5 \\ 3-3i \end{pmatrix} e^t(\cos(\tfrac{3}{2}t) + i\sin(\tfrac{3}{2}t))$$

$$= e^t \left[\begin{pmatrix} 5(\cos(\frac{3}{2}t) + i\sin(\frac{3}{2}t)) \\ (3-3i)(\cos(\frac{3}{2}t) + i\sin(\frac{3}{2}t)) \end{pmatrix} \right]$$

$$= e^t \left[\begin{pmatrix} 5\cos(\frac{3}{2}t) \\ 3\cos(\frac{3}{2}t) + 3\sin(\frac{3}{2}t) \end{pmatrix} + i \begin{pmatrix} 5\sin(\frac{3}{2}t) \\ 3\sin(\frac{3}{2}t) - 3\cos(\frac{3}{2}t) \end{pmatrix} \right]$$

$$= c_1 e^t \left[\begin{pmatrix} 5\cos(\frac{3}{2}t) \\ 3\cos(\frac{3}{2}t) + 3\sin(\frac{3}{2}t) \end{pmatrix} \right] + c_2 e^t \left[\begin{pmatrix} 5\sin(\frac{3}{2}t) \\ 3\sin(\frac{3}{2}t) - 3\cos(\frac{3}{2}t) \end{pmatrix} \right]$$

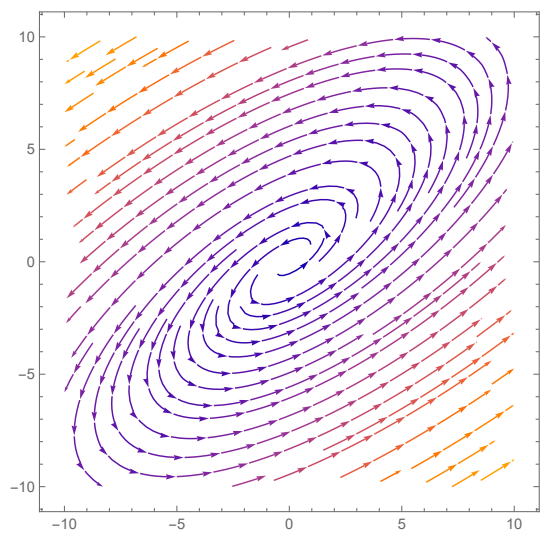
$$= c_1 e^t \left[\begin{pmatrix} 5 \\ 3 \end{pmatrix} \cos(\tfrac{3}{2}t) - \begin{pmatrix} 0 \\ -3 \end{pmatrix} \sin(\tfrac{3}{2}t) \right] + c_2 e^t \left[\begin{pmatrix} 0 \\ -3 \end{pmatrix} \cos(\tfrac{3}{2}t) + \begin{pmatrix} 5 \\ 3 \end{pmatrix} \sin(\tfrac{3}{2}t) \right]$$

Notice that the vectors in front of the sins and cosines are components of the eigenvector that we started with:

$$\mathbf{v}_1 = \begin{bmatrix} 5 \\ 3-3i \end{bmatrix} = \begin{bmatrix} 5 \\ 3 \end{bmatrix} + i \begin{bmatrix} 0 \\ -3 \end{bmatrix}$$

This is a spiral source, so all trajectories will spiral outwards from the origin.

Notice that with another example, our hypothesized shortcut still works! This is pretty cool, so maybe we can just use this formula for any complex eigenvalues we get in the future and save ourselves a lot of time!



Question 2:

Find the general solution of the 3D System:

$$\mathbf{x}'(t) = \begin{pmatrix} 1 & 1 & 2 \\ 1 & 2 & 1 \\ 2 & 1 & 1 \end{pmatrix} \mathbf{x}(t)$$

$$\begin{vmatrix} 1-\lambda & 1 & 2 \\ 1 & 2-\lambda & 1 \\ 2 & 1 & 1-\lambda \end{vmatrix} = (1-\lambda)\begin{vmatrix} 2-\lambda & 1 \\ 1 & 1-\lambda \end{vmatrix} - 1\begin{vmatrix} 1 & 1 \\ 2 & 1-\lambda \end{vmatrix} + 2\begin{vmatrix} 1 & 2-\lambda \\ 2 & 1 \end{vmatrix}$$

$$= (1-\lambda)\left[(2-\lambda)(1-\lambda)-1\right] - 1[(1-\lambda)-2] + 2[1-2(2-\lambda)] = 0$$

$$= (1-\lambda)(1-3\lambda+\lambda^2) + (1+\lambda) + (-6+4\lambda) = 0$$

$$= 1 - 3\lambda + \lambda^2 - \lambda + 3\lambda^2 - \lambda^3 - 5 + 5\lambda = 0$$

$$= -\lambda^3 + 4\lambda^2 + \lambda - 4 = 0$$

$$= \lambda^3 - 4\lambda^2 - \lambda + 4 = 0$$

$$= (\lambda^3 - 4\lambda^2) - (\lambda - 4) = 0$$

$$= \lambda^2(\lambda - 4) - (\lambda - 4) = 0$$

$$= (\lambda^2 - 1)(\lambda - 4) = 0$$

So our eigenvalues are: $\lambda_1 = 4, \lambda_2 = 1, \lambda_3 = -1$

Eigenvalue #1

$$\lambda_{\mathbf{1}} = \quad \mathbf{4}: \begin{bmatrix} 1-\lambda_1 & 1 & 2 \\ 1 & 2-\lambda_1 & 1 \\ 2 & 1 & 1-\lambda_1 \end{bmatrix} = \begin{bmatrix} -3 & 1 & 2 \\ 1 & -2 & 1 \\ 2 & 1 & -3 \end{bmatrix} \xrightarrow{\text{RREF}} \begin{bmatrix} 1 & 0 & -1 \\ 0 & 1 & -1 \\ 0 & 0 & 0 \end{bmatrix}$$

$$\text{This gives us that } \begin{cases} a &= c \\ b &= c \\ c &= c \end{cases} \text{ so our eigenvalue is } \mathbf{u}_1 = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

Eigenvalue #2

$$\lambda_{\mathbf{2}} = \quad \mathbf{1}: \begin{bmatrix} 1-\lambda_2 & 1 & 2 \\ 1 & 2-\lambda_2 & 1 \\ 2 & 1 & 1-\lambda_2 \end{bmatrix} = \begin{bmatrix} 0 & 1 & 2 \\ 1 & 1 & 1 \\ 2 & 1 & 0 \end{bmatrix} \xrightarrow{\text{RREF}} \begin{bmatrix} 1 & 0 & -1 \\ 0 & 1 & 2 \\ 0 & 0 & 0 \end{bmatrix}$$

$$\text{This gives us that } \begin{cases} a &= c \\ b &= -2c \\ c &= c \end{cases} \text{ so our eigenvalue is } \mathbf{u}_2 = \begin{bmatrix} 1 \\ -2 \\ 1 \end{bmatrix}$$

Eigenvalue #3

$$\lambda_{\mathbf{3}} = -\mathbf{1}: \begin{bmatrix} 1-\lambda_3 & 1 & 2 \\ 1 & 2-\lambda_3 & 1 \\ 2 & 1 & 1-\lambda_3 \end{bmatrix} = \begin{bmatrix} 2 & 1 & 2 \\ 1 & 3 & 1 \\ 2 & 1 & 2 \end{bmatrix} \xrightarrow{\text{RREF}} \begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

$$\text{This gives us that } \begin{cases} a &= -c \\ b &= 0 \\ c &= c \end{cases} \text{ so our eigenvalue is } \mathbf{u}_3 = \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix}$$

Thus, the general solution to our system is

$$\mathbf{x}(t) = c_1 e^{4t} \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} + c_2 e^{t} \begin{bmatrix} 1 \\ -2 \\ 1 \end{bmatrix} + c_3 e^{-t} \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix}$$

Question 3:

Consider the equation $ay'' + by' + cy = 0$ with a, b, c are constants and $a \neq 0$. The general solution depends on the roots of the characteristic equation ar^2+br+c

a) Given $x_1 = y, x_2 = y'$, we can then also say that $x_1' = y' = x_2$ and $x_2' = y''$ so we can rewrite our original equation as $ax_2' + bx_2 + cx_1 = 0$
Solving for the derivative we obtain $x_2' = -\dfrac{b}{a}x_2 - \dfrac{c}{a}x_1$ with $x_1' = x_2$
Thus, we can write our system as $\mathbf{x}' = \begin{pmatrix} 0 & 1 \\ -\frac{c}{a} & -\frac{b}{a} \end{pmatrix} \mathbf{x}$

b) Now let's find the eigenvalues of this system:
$$\begin{vmatrix} -\lambda & 1 \\ -\frac{c}{a} & -\frac{b}{a} - \lambda \end{vmatrix} = (-\lambda)(-\frac{b}{a} - \lambda) + \frac{c}{a} = 0$$
$$= \lambda^2 + \frac{b}{a}\lambda + \frac{c}{a} = a\lambda^2 + b\lambda + c = 0$$
Notice that this is the same characteristic equation as our original second order ODE, so the eigenvalues are just the roots of the characteristic equation.

Question 4:

Consider the system:

$$\mathbf{x}' = \begin{pmatrix} -1 & -1 \\ -\alpha & -1 \end{pmatrix} \mathbf{x}$$

a) Solve the system for $\alpha = 0.5$ What are the eigenvalues? Classify the equilibrium at the origin.

$$\begin{vmatrix} -1-\lambda & -1 \\ -0.5 & -1-\lambda \end{vmatrix} = (-1-\lambda)^2 - (-1)(-0.5) = 0$$

$$= 1 + 2\lambda + \lambda^2 - 0.5 = 0$$

$$= \lambda^2 + 2\lambda + 0.5 = 0$$

$$\Rightarrow \lambda_1 = -1 + \tfrac{\sqrt{2}}{2}, \lambda_2 = -1 - \tfrac{\sqrt{2}}{2}$$

Eigenvalue #1

$$\boldsymbol{\lambda_1 = -1 + \tfrac{\sqrt{2}}{2}} : \begin{bmatrix} -1-\lambda_1 & -1 \\ -0.5 & -1-\lambda_1 \end{bmatrix} \to \begin{bmatrix} -\frac{\sqrt{2}}{2} & -1 \\ -0.5 & -\frac{\sqrt{2}}{2} \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{aligned} -\tfrac{1}{\sqrt{2}}v_1 - 1v_2 &= 0 \\ -0.5v_1 - \tfrac{1}{\sqrt{2}}v_2 &= 0 \end{aligned} \longrightarrow \quad v_1 = -\sqrt{2}v_2 \quad \longrightarrow \mathbf{v}_1 = \begin{bmatrix} -\sqrt{2} \\ 1 \end{bmatrix}$$

Eigenvalue #2

$$\boldsymbol{\lambda_2 = -1 - \tfrac{\sqrt{2}}{2}} : \begin{bmatrix} -1-\lambda_2 & -1 \\ -0.5 & -1-\lambda_2 \end{bmatrix} \to \begin{bmatrix} \frac{\sqrt{2}}{2} & -1 \\ -0.5 & \frac{\sqrt{2}}{2} \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{aligned} \tfrac{1}{\sqrt{2}}v_1 - 1v_2 &= 0 \\ -0.5v_1 + \tfrac{1}{\sqrt{2}}v_2 &= 0 \end{aligned} \longrightarrow \quad v_1 = \sqrt{2}v_2 \quad \longrightarrow \mathbf{v}_1 = \begin{bmatrix} \sqrt{2} \\ 1 \end{bmatrix}$$

So our general solution is $\mathbf{x} = c_1 \begin{pmatrix} -\sqrt{2} \\ 1 \end{pmatrix} e^{(-1+\frac{\sqrt{2}}{2})t} + c_2 \begin{pmatrix} \sqrt{2} \\ 1 \end{pmatrix} e^{(-1-\frac{\sqrt{2}}{2})t}$

The equlibrium at the origin is a stable sink node, since both eigenvalues are negative and real.

b) Repeat for $\alpha = 2$

$$\begin{vmatrix} -1-\lambda & -1 \\ -2 & -1-\lambda \end{vmatrix} = (-1-\lambda)^2 - (-1)(-2) = 0$$

$$= 1 + 2\lambda + \lambda^2 - 2 = 0$$

$$= \lambda^2 + 2\lambda - 1 = 0$$

$$\Rightarrow \lambda_1 = -1 + \sqrt{2}, \lambda_2 = -1 - \sqrt{2}$$

Eigenvalue #1

$$\boldsymbol{\lambda_1 = -1 + \sqrt{2}} : \begin{bmatrix} -1-\lambda_1 & -1 \\ -2 & -1-\lambda_1 \end{bmatrix} \to \begin{bmatrix} -\sqrt{2} & -1 \\ -2 & -\sqrt{2} \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{aligned} -\sqrt{2}v_1 - 1v_2 &= 0 \\ -2v_1 - \sqrt{2}v_2 &= 0 \end{aligned} \longrightarrow \quad v_2 = -\sqrt{2}v_1 \quad \longrightarrow \mathbf{v}_1 = \begin{bmatrix} 1 \\ -\sqrt{2} \end{bmatrix}$$

Eigenvalue #2

$$\boldsymbol{\lambda_2 = -1 - \sqrt{2}} : \begin{bmatrix} -1-\lambda_2 & -1 \\ -2 & -1-\lambda_2 \end{bmatrix} \to \begin{bmatrix} \sqrt{2} & -1 \\ -2 & \sqrt{2} \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{aligned} \sqrt{2}v_1 - 1v_2 &= 0 \\ -2v_1 + \sqrt{2}v_2 &= 0 \end{aligned} \longrightarrow \quad v_2 = \sqrt{2}v_1 \quad \longrightarrow \mathbf{v}_1 = \begin{bmatrix} 1 \\ \sqrt{2} \end{bmatrix}$$

So our general solution is $\mathbf{x} = c_1 \begin{pmatrix} 1 \\ -\sqrt{2} \end{pmatrix} e^{(-1+\sqrt{2})t} + c_2 \begin{pmatrix} 1 \\ \sqrt{2} \end{pmatrix} e^{(-1-\sqrt{2})t}$

The equlibrium at the origin is a unstable saddle, since we have one positive and one negative real eigenvalue.

c) Find the eigenvalues in terms of α and determine the value of α between 0.5 and 2 where the transition from one type of behavior to the other occurs.

$$\begin{vmatrix} -1-\lambda & -1 \\ -\alpha & -1-\lambda \end{vmatrix} = (-1-\lambda)^2 - \alpha = 0$$

$$\rightarrow (-1-\lambda)^2 = \alpha$$

$$\rightarrow -1-\lambda = \pm\sqrt{\alpha}$$

$$\rightarrow -1-\lambda = \pm\sqrt{\alpha}$$

$$\rightarrow \lambda_1 = -1+\sqrt{\alpha}, \lambda_2 = -1-\sqrt{\alpha}$$

We can see that $\lambda_1 > \lambda_2$ for all $\alpha > 0$. Notice that for all values of α, λ_2 is always negitive, but the same cant be said for λ_1. So the transition from stable to unstable behavior occurs when λ_1 goes from negative to positive, which happens at $\alpha = 1$. Any values of α between 0 and 1 will give us both negitive eigenvalues, meaning the origin is a stable sink node, and any values of α between 1 and 2 will give us an unstable saddle since we will obtain one positive and one negative eigenvalue.
